| Layer7<br>Transparent Proxy                   | The Load-Balancer acts as a Reverse-Proxy between the client and the server.<br>Two TCP connections are established:<br>1. One between the client and the Load-Balancer<br>2. One between the Load-Balancer and the server<br>The Load-Balancer spoofs the client IP address when establishing the TCP connection to the server.   | Src: client IP<br>Dst: service VIP<br>Src: service VIP<br>Dst: client IP<br>Dst: client IP<br>Dst: client IP<br>Dst: client IP<br>Dst: client IP   | <ul> <li>improve security</li> <li>allows protocol inspection<br/>and validation</li> <li>servers know the client<br/>IP at TCP layer</li> </ul>   | <ul> <li>intrusive: the traffic from the server to the client must pass through the Load-Balancer</li> <li>clients and servers can't be in the same subnet/vlan</li> <li>takes more resources than L4 modes</li> <li>bandwidth limited by Load-balancer capacity</li> </ul> | <ul> <li>application layer advanced features</li> <li>SSL offloading</li> <li>improve application protection</li> <li>client IP address mandatory at TCP layer</li> </ul> |  |
| Layer4<br>Destination NAT                     | In <b>Destination NAT</b> mode, the <b>Load-balancer</b> forwards packets between <b>clients</b> and <b>servers</b> by changing the destination IP address of each packets. The TCP connection is established directly between the <b>client</b> and the <b>server</b> .   | Src: client IP<br>Dst: service VIP<br>ALOHA<br>Src: service VIP<br>Dst: client IP<br>Dst: server IP<br>Dst: client IP<br>Dst: client IP  | <ul> <li>fast load-balancing</li> <li>servers know the client<br/>IP address at the TCP<br/>layer</li> <li>allows millions of connec-<br/>tions</li> </ul>   | <ul> <li>intrusive: the traffic from the server to the client must pass through the Load-Balancer</li> <li>clients and servers can't be in the same subnet/vlan</li> <li>bandwidth limited by Load-balancer capacity</li> </ul>   | <ul> <li>when response time matters</li> <li>when nothing but the default gateway of the servers can be changed</li> </ul>  |  |
| Layer4<br>Full NAT                            | In full NAT mode, the Load-Balancer forwards packets between clients<br>and servers by changing both source IP and destination IP address of<br>each packet.<br>The TCP connection is established directly between a client and a server.  | Src: client IP<br>Dst: service VIP<br>Src: service VIP<br>Dst: client IP<br>Dst: server IP<br>Src: server IP<br>Dst: client IP<br>Dst: server IP<br>Dst: server IP<br>Dst: server IP                     | <ul> <li>fast load-balancing</li> <li>non intrusive</li> <li>clients and servers can<br/>be in the same sub-<br/>net/vlan</li> </ul>   | <ul> <li>servers don't know the client IP<br/>address at the TCP layer</li> <li>bandwidth limited by Load-<br/>Balancer capacity</li> </ul>   | <ul> <li>when response time matters</li> <li>very simple deployment</li> </ul>  |  |
| Layer4<br>DSR or gateway                      | DSR stands for Direct Server Return<br>In DSR mode, the Load-Balancer forwards packets to the servers without<br>changing anything in it but the destination MAC address: the new MAC<br>address is server one.<br>Two asymmetric flows happen:<br>1. Inbound: client ==> Load-Balancer ==> Server<br>2. Outbound: server ==> client<br>The servers must have the service IP configured on a loopback to be able<br>to accept the requests.                | Src: client IP<br>Dst: service VIP<br>ALOHA<br>Src: client IP<br>Dst: service VIP<br>Dst: service VIP<br>Dst: service VIP<br>Dst: service VIP<br>Dst: service VIP  | <ul> <li>fast load-balancing</li> <li>allows millions of connections</li> <li>allows huge outbound bandwidth</li> <li>servers know the client IP address at the TCP layer</li> <li>clients and servers can be in the same subnet/vlan</li> </ul>   | <ul> <li>intrusive: service IP must be configured on a loopback in each server</li> <li>The Load-Balancer must have an interface in the server vlan</li> </ul>  | <ul> <li>when response time matters</li> <li>when bandwidth matters</li> </ul>  |  |
| Layer4<br>IP Tunnel                           | The IP tunnel mode looks like the DSR mode, except that traffic between<br>the load-balancer and the server can be routed.<br>The load-balancer encapsulates the client packet in an IP tunnel established<br>with the server.<br>Two asymmetric flows happen:<br>1. Inbound: client ==> Load-Balancer ==> Server<br>2. Outbound: server ==> client<br>The servers must have the service IP configured on a loopback to be able<br>to accept the requests. | Src: client IP<br>Dst: service VIP<br>Src: client IP<br>Dst: service VIP<br>Client packet encapsulated   | <ul> <li>fast load-balancing</li> <li>allows millions of connections</li> <li>servers know the client IP address at the TCP layer</li> <li>clients and servers can be in the same subnet/vlan</li> </ul>   | <ul> <li>intrusive: an IP tunnel must be setup between the Load-Balancer and the server</li> <li>intrusive: service IP must be configured on a loopback in each server</li> <li>The Load-Balancer must have an interface in the server vlan</li> </ul>                      | <ul> <li>when response time matters</li> <li>when bandwidth matters</li> <li>when the load-balancer can't have an interface in the server vlan</li> </ul>                 |  |
| Layer4 / Layer7<br>Transparent listen-<br>ing | This mode is also known as VIPless.<br>The service IP is not configured on the Load-Balancer itself, but it is<br>routed by the routers to the Load-Balancer.<br>The Load-Balancer will match traffic on the fly, applying any of the Load-<br>Balancing rules. It is compatible with all modes above.   |  | <ul> <li>affect only client to Load-Balancer traffic</li> <li>A single vrrp IP address per Load-Balancer cluster is required, whatever the number of service IP it hosts</li> <li>adding new service IPs means adding a route on the core routers</li> <li>the Load-Balancer can be hidden and unreachable from internet while load-balancing</li> </ul> | <ul> <li>requires networking skills</li> <li>the service IP address can't be<br/>pinged since not configured any-<br/>where</li> </ul>  | • when a huge number of <b>service IP</b> is required   |  |
